

Divide and Conquer

Prune and Search

Divide and Conquer

- ▶ **Termination**: If the problem is small enough, then solve it directly.
- ▶ **Divide**: Break-down the problem into one or more subproblems.
- ▶ **Conquer**: Solve the subproblems
- ▶ **Combine**: Compute the solution by combining the solutions of subproblems

Long Multiplication

$\begin{array}{r} 234 \\ \times 123 \\ \hline 702 \\ 468 \\ 234 \\ \hline 28782 \end{array}$	$\begin{array}{r} 234 \\ \times 3 \\ \hline 12 \\ 9 \\ 6 \\ \hline 702 \end{array}$	$\begin{array}{r} 234 \\ \times 2 \\ \hline 8 \\ 6 \\ 4 \\ \hline 468 \end{array}$	$\begin{array}{r} 234 \\ \times 1 \\ \hline 4 \\ 3 \\ 2 \\ \hline 234 \end{array}$
--	---	--	--

Long Multiplication

- ▶ **Termination:** $x, y \in \{0, \dots, 9\}$
- ▶ **Divide:** If $y = y_n \dots y_0 \geq 10$, then divide the problem into $x \times y_n, \dots, x \times y_0$. If $x = x_m \dots x_0 \geq 10$ and $y < 10$, then divide the problem into $x_m \times y, \dots, x_0 \times y$.
- ▶ **Conquer:** Solve the subproblems
- ▶ **Combine:** Compute $\sum_{0 \leq i \leq n} x \times y_i \times 10^i$ for the first case or $\sum_{0 \leq j \leq m} x_j \times y \times 10^j$ for the second.

Faster Multiplication

- ▶ Andrey Kolmogorov conjectured multiplication takes $\Omega(nm)$ in 1952.
- ▶ In 1960, a 23-year-old student, Anatolii Alexeevitch Karatsuba, found a simple $O(n^{1.59})$ -time algorithm.
- ▶ Toom–Cook: $O(n^{\log(2k-1)/\log k})$

Karatsuba Algorithm

- ▶ Let $x = x_H B + x_L$ and $y = y_H B + y_L$ where $x_L < B$, $y_L < B$, and $y \leq x < B^2$.
- ▶ $xy = x_H y_H B^2 + x_L y_H B + x_H y_L B + x_L y_L$.
- ▶ 4 subproblems $x_H y_H$, $x_L y_H$, $x_H y_L$, $x_L y_L$.
- ▶ $T(n) = 4T(n/2) + O(n) = O(n^2)$
- ▶ Karatsuba's Goal: reduce the number of subproblems to 3!

Karatsuba Algorithm

- ▶ $z = z_H B^2 + z_M B + z_L$
 $= xy = x_H y_H B^2 + x_L y_H B + x_H y_L B + x_L y_L$
- ▶ $z_H = x_H y_H$ and $z_L = x_L y_L$
- ▶ $z_M = x_L y_H + x_H y_L$
 $= (x_H + x_L) \times (y_H + y_L) - x_H y_H - x_L y_L$
 $= (x_H + x_L) \times (y_H + y_L) - z_H - z_L$

Karatsuba Algorithm

- ▶ **Termination:** If x and y are small, multiply them by long multiplication.
- ▶ **Divide:** $x_H \times y_H$, $x_L \times y_L$, $(x_H + x_L) \times (y_H + y_L)$
- ▶ **Conquer:** Solve the subproblems
- ▶ **Combine:** Let $z_H = x_H y_H$, $z_L = x_L y_L$, $z_M = (x_H + x_L) \times (y_H + y_L) - z_H - z_L$, and $x \times y = z_H B^2 + z_M B + z_L$.
- ▶ **Time:** $T(n) = 3T(n/2) + O(n) = O(n^{1.59})$

Quick Sort

Sort $A[1], \dots, A[n]$

- ▶ **Termination**: It is sorted when $n=1$.
- ▶ **Divide**: Reorder A and find m such that
 - ▶ For $i < m$, $A[i] \leq A[m]$.
 - ▶ For $i > m$, $A[i] \geq A[m]$.
- ▶ **Conquer**: Sort $A[1..m-1]$ and $A[m+1..n]$.
- ▶ **Combine**: No need.
- ▶ **Time**: $T(n) = T(m-1) + T(n-m) + O(n)$

Partition

Partition

If $A[P] < A[L]$:
 $\text{swap}(A[L], A[R])$
 $R = R - 1$

 $\text{swap}(A[P], A[R])$
 $P = P - 1, R = R - 1$

$\text{qsort}(A[1..R])$
 $\text{qsort}(A[L..n])$

Quick Sort

- ▶ Worst case:

- ▶ $T(n) = T(n-1) + O(n) = O(n^2)$

- ▶ Average case:

- ▶ What is average? The input sequence is uniformly randomly sampled.

- ▶ $T(n) = (2/n)(T(1) + \dots + T(n-1)) + O(n)$
 $= O(n \log n)$

Merge Sort

- ▶ **Input:** $\langle a_1, \dots, a_n \rangle$
- ▶ **Termination:** $n=1$. $\langle a_1 \rangle$ is sorted.
- ▶ **Divide:** split $\langle a_1, \dots, a_n \rangle$ into $\langle a_1, \dots, a_{n/2} \rangle$ and $\langle a_{1+n/2}, \dots, a_n \rangle$.
- ▶ **Conquer:** Sort $\langle a_1, \dots, a_{n/2} \rangle$ and $\langle a_{1+n/2}, \dots, a_n \rangle$
- ▶ **Combine:** Merge two sorted lists into a sorted list $\langle b_1, \dots, b_n \rangle$

Decrease and Conquer

- ▶ A special case of divide and conquer
 - ▶ There is only one subproblem.
- ▶ For example: Greatest common divisor
 - ▶ $\text{GCD}(a, 0) = a$
 - ▶ $\text{GCD}(a, b) = \text{GCD}(b, a)$... use this if $a < b$
 - ▶ $\text{GCD}(a, b) = \text{GCD}(a - b, b)$

Prune and Search

- ▶ A special case of decrease and conquer
- ▶ $T(n) = T(pn) + O(f(n))$ where $p < 1$
- ▶ Example:
 - ▶ Binary search
 - ▶ Bisection method
 - ▶ Golden section search
 - ▶ Extended Euclidean algorithm

Binary search

- ▶ Given x and a **sorted** array $A[1..n]$.
- ▶ If $x \in A$, then find out **k** such that $x = A[k]$.
- ▶ If $x \notin A$, then find out **k** such that $A[k-1] < x < A[k]$.
(Suppose $A[0] = -\infty$ and $A[n+1] = \infty$.)

Binary search

- ▶ Strategy:
 - ▶ If $n=1$, then return if $A[1]=x$.
 - ▶ Suppose there are n elements in A , check if $A[n/2]=x$.
 - ▶ If $A[n/2] \neq x$, then check if $A[n/2] < x$.
 - ▶ Y: $k = \text{bSearch}(A[0..(n/2)], x)$
 - ▶ N: $k = n/2 + \text{bSearch}(A[(n/2)+1..(n+1)], x)$
- ▶ Can be done in $O(\log n)$
- ▶ Iterative implementation?
